

# Arduino: Enabling the Internet of Things [2009-04-05]

## Overview

The [Arduino](#)<sup>1</sup> is a micro-controller platform ([AVR ATmega](#)<sup>2</sup>) constructed completely from open-source hardware and software. Since the Arduino is open, inexpensive, easy to acquire and very easy to use ... it has become quite popular amongst the hacker community.

There are many different [Arduino form-factors](#)<sup>3</sup> (development boards, just the bare-bones chip and even wearable). There are also many communications options ([USB](#)<sup>4</sup>, [Ethernet](#)<sup>5</sup>, [Bluetooth](#)<sup>6</sup> and [ZigBee](#)<sup>7</sup>, I2C, SPI and more). In all cases, the designated low-level use of the micro-controller pin-outs, the software development environment and run-time environment are effectively the same. However, if the Arduino isn't powerful enough, you can use the 32-bit ARM Cortex M3 powered [Cortino](#)<sup>8</sup> and still maintain the same Arduino development board form-factor and pin-outs.

This combination of standardization over a number of levels and flexibility has been the catalyst for a significant number of projects and examples based on the Arduino.

## Creating a higher-level standard for Arduino run-time examples (a mini-framework)

Many of the on-line Arduino projects and examples focus on connecting just one piece of hardware to an Arduino. This isn't a bad thing, because they have helped us all get into our Arduinos much faster (thanks everyone !).

Unfortunately, when you try to combine aspects of different examples, you'll find overlaps between the pin-out usage and various software fragments that just don't work well together. The examples aren't modular (componentized) and often use simple large delay loops (rather than timers or interrupts), because of an implicit assumption that one example doesn't have to share the processor (or run-time environment) with other examples.

Wouldn't it be excellent, if there was some higher-level standardization across Arduino examples that allowed you to cherry-pick what you needed and plug them together quickly ?

For example, I'd like to grab a [one-wire](#)<sup>9</sup> [temperature sensor](#)<sup>10</sup>, a [light sensor](#)<sup>11</sup>, an [LCD display](#)<sup>12</sup> and wirelessly transmit the results using [VirtualWire](#)<sup>13</sup> ... and quickly have this working.
